

# Brand guide

Colour, mark, shape and voice — and the one rule that keeps the product honest.

Version 1.5.0 · generated 21 September 2026 from the source files that define these values. The code is the source of truth; regenerate with `node scripts/make-brand-guide.mjs`.

THE ONE RULE

**The brand colour and the data colours are separate systems.**  
**Neither may borrow from the other.**

A colour on a chart is a claim about which measurement you are looking at. If the app's chrome uses the same colour, the claim stops being trustworthy.

This has already gone wrong once. Until version 1.4.0 the accent was #818cf8 — and so was the Mood domain. The same hex, in 71 places: one meant Mood, seventy meant "this is a button".

Reaching for a colour to identify a **measurement**? `src/lib/domains.ts`. For a **control, link or surface**? `src/constants/brand.ts`. An unrecognised factor takes the neutral #8892a4 and must never fall back to the brand.

THE MARK

An **S** cut from a gradient of the domain colours: the mark is literally made of the palette the app measures with. Do not flatten it, re-order the stops, or recolour it for a campaign.

| CONTEXT                     | TILE        | GLYPH FILLS               |
|-----------------------------|-------------|---------------------------|
| In-app lockup               | #2A251C     | 41%                       |
| Launcher icon               | #2A251C     | 58%                       |
| Android adaptive foreground | transparent | 50%, inside the safe zone |
| Splash                      | transparent | 88%                       |

One tile, on both. The launcher used the accent's fill until 1.5.0, on the reasoning that an almost-black icon disappears on a dark wallpaper. Measuring it killed the rule: the mark is seven light, saturated colours, so what it needs is a dark ground. The worst gradient stop manages **1.3:1** on the porcelain fill against **5.6:1** on the tile.

Every icon is generated from the component by `scripts/make-icons.mjs`. Regenerate, never redraw.

A warm off-white, #E7E2D9, under a near-black label. It is the default because it is the only accent that cannot collide with a data colour under any circumstance: it has no hue to collide with.

Two others ship with it and are the user's to pick in Settings — see the next page. Everything unqualified in this guide is porcelain, because that is what the launcher icon, the splash and the notification tint are baked with.

**fill**  
#E7E2D9  
Primary button.  
on #0a0c12 **15.2:1** label on it **15.2:1** nearest data **ΔE 35**

**onFill**  
#0A0C12  
The label on fill, fillAlt and signIn. Never hard-code it.  
on #0a0c12 **1.0:1** label on it **15.2:1**

| opacity | 0.25                                                                              | 0.15                                                                              | 0.1                                                                               | 0.06                                                                              |
|---------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| solid   |  |  |  |  |

**text**  
#C8B79A  
Links, icons, active labels.  
on #0a0c12 **10.0:1** label on it **10.0:1** nearest data **ΔE 37**

| opacity | 0.25                                                                                | 0.15                                                                                | 0.1                                                                                 | 0.06                                                                                |
|---------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| solid   |  |  |  |  |

**fillAlt**  
#CFC7B6  
Gradient partner and secondary fills.  
on #0a0c12 **11.6:1** label on it **11.6:1** nearest data **ΔE 32**

**textSoft**  
#DACEB8  
Larger or lower-emphasis accent text.  
on #0a0c12 **12.6:1** label on it **12.6:1** nearest data **ΔE 36**

**textFlat**  
#B5A386  
Settings accents, a touch flatter.  
on #0a0c12 **8.0:1** label on it **8.0:1** nearest data **ΔE 36**

## BRAND COLOUR, CONTINUED

|                                                                                   |                                                                                                                                                             |

## IN PLACE

## WASHES

Translucent accents go through `brandTint(BRAND.x, alpha)`. Never hand-write `rgba(...)`: forty-three of those were the reason the last colour change could not be done with search and replace, because raw channel numbers have no textual link to the colour they are a tint of.

## THE ACCENT IS THE USER'S

Three options, set in Settings and stored on the profile so they follow the person between devices. Porcelain is the default.

The reasoning is the same one that produced comfort mode. This app is used daily, often for years, often by someone who feels bad. What colour the chrome is carries no information at all, so handing that one piece back costs nothing. What is *not* negotiable is the data palette: every chart makes its argument in colour, so those stay fixed whichever accent is on.

### Porcelain DEFAULT

fill #E7E2D9 label 15.2:1 text #C8B79A at 10.0:1 nearest data ΔE 37

### Teal

fill #0F6E56 label 6.2:1 text #4FD1C5 at 10.5:1 nearest data ΔE 27

### Plum

fill #7A1A82 label 9.1:1 text #DDA0E8 at 9.6:1 nearest data ΔE 26

## WHAT A NEW ACCENT HAS TO CLEAR

scripts/check-accents.mjs parses the real palette and fails on any of these, so the list is enforced rather than aspirational:

- Accent text reads **4.5:1** on #0a0c12 (3:1 for textSoft, which is only used large).
- Each fill's paired label reads **4.5:1** on it. This is why every accent carries its own onFill: white on porcelain is 1.3:1.
- Nothing lands within **ΔE 15** of a domain colour.
- No accent text lands within **ΔE 15** of body text #e2e8f0, or a link stops looking like a link. This is the check that moved porcelain's text off the obvious off-white #D6CFC2, which measured ΔE 14.6.
- The three fills sit at least **ΔE 25** apart, or the setting does nothing visible.

## DATA COLOUR — MIND DOMAINS

---

These identify measurements. They are not brand colours and change only if the meaning changes.

|                                                                                                                         |                                                                                                                    |
|-------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
|  <b>mood</b><br>#818CF8                |  <b>energy</b><br>#34D399         |
|  <b>anxiety</b><br>#FB923C             |  <b>concentration</b><br>#38BDF8  |
|  <b>irritability</b><br>#F472B6        |  <b>social battery</b><br>#A78BFA |
|  <b>sensory sensitivity</b><br>#FBBF24 |  <b>motivation</b><br>#C084FC     |
|  <b>sleep</b><br>#7B9EB8               |                                                                                                                    |

## DATA COLOUR — BODY, AND THE NEUTRAL

---

|                                                                                                                      |                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
|  <b>all body domains</b><br>#BC812F |  <b>unknown factor</b><br>#8892A4 |
|----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|

Every body domain shares one colour, because body domains are read as a group against mind.

## ADDING A DOMAIN COLOUR

---

Check it against the brand tokens *and* every existing domain using perceptual distance, not hue. Under **ΔE 15** is confusable at a glance. Hue alone will mislead you: a dark teal and a bright mint are 17° apart and never mistaken for each other.

For reference, the current brand fill sits ΔE 35 from the nearest data colour (sleep), and the link text ΔE 37 from sleep.

## COMFORT MODE

---

A muted version of whichever accent is on, for users who find the normal one too loud, plus a 1.15× type scale. Each accent carries its own quiet set rather than having one computed by formula: pulling chroma back by a fixed ratio works for a saturated teal and falls apart for porcelain, which is already near-white and gets quieter by going *down* in lightness.

Shown here for porcelain.

|                                                                                                                      |                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
|  <b>comfort fill</b><br>#BDB4A5   |  <b>comfort text</b><br>#A99C86 |
|  <b>comfort border</b><br>#2E2921 |                                                                                                                    |

## PRINT COLOUR

---

The PDF report has its own palette and does not use the app's tokens. **A screen colour chosen for a near-black background can be invisible on white** — the brand's #C8B79A manages 2.0:1 there.

|                                                                                   |                                      |                                                                                   |                                   |
|-----------------------------------------------------------------------------------|--------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------|
|  | <b>ink</b><br>#1F2937                |  | <b>muted</b><br>#6B7280           |
|  | <b>rules</b><br>#D1D0C8              |  | <b>teal — improved</b><br>#0F6E56 |
|  | <b>coral — concerning</b><br>#A32D2D |  | <b>amber — watch</b><br>#854F0B   |

## SHAPE

---

|                |                                                          |
|----------------|----------------------------------------------------------|
| <b>8pt</b>     | Chips, pills, tabs, filter controls, buttons — specified |
| <b>10–16pt</b> | Cards and inputs — in practice; see below                |
| <b>20–24pt</b> | Hero cards and modals                                    |
| <b>Circles</b> | Stay circles: PIN keypad, comfort button, icon badges    |

Controls were capsule-shaped until 1.4.0. Eight reads as a control rather than a tag, and echoes the cards behind it. That is the one radius this guide actually specifies.

**The card radii are not yet a scale.** The codebase uses 10 in 44 places, 12 in 43, 16 in 22 and 14 in 15, plus a long tail — the values arrived with the components that were ported, not from a decision. Documented here as what is true rather than as a three-step scale that nothing follows. Normalising them is an open job, not a rule anyone is currently breaking.

## TYPOGRAPHY

---

**There is no brand typeface, and this is a known gap.** The app uses each platform's system font. The report asks for Roboto, "Noto Sans", Helvetica, Arial — Roboto first so Android's substitution is deliberate rather than accidental.

This matters more than it sounds: Android has neither Helvetica nor Arial, and the same report paginated differently on the two platforms — five of eleven pages overflowed under an Android-like font while all eleven fitted under Helvetica. Page budgets are fitted to the wider of the two. Adding a typeface means re-running `scripts/report-layout/`.

VOICE

Calm, plain-spoken, low-hype. No exclamation points, no emoji, no empowerment language. Speaks like a competent friend, not a wellness brand. Sentences say what will happen — "takes about 20 seconds each time" — rather than selling a feeling.

|                                                                                                                                                                                                         |                                                                                                                                                                                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Do</b> <ul style="list-style-type: none"><li>• Say what was measured, and over how many days</li><li>• Let a null result be a result</li><li>• Treat a baseline as typical for that person</li></ul> | <b>Don't</b> <ul style="list-style-type: none"><li>• Imply cause from correlation</li><li>• Call a baseline "fine" or "normal"</li><li>• Congratulate someone on their symptoms</li></ul> |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

The audience is managing a chronic illness, has often been dismissed for years, and has been sold to enough.

ACCESSIBILITY

Floors: **4.5:1** for body text, **3:1** for large or bold. Every brand token meets them in the direction it is used. Colour is never the only signal — charts carry labels and numbers, findings carry a confidence word as well as a tier colour.

| PAIRING                        | RATIO         |
|--------------------------------|---------------|
| White on brand fill            | <b>1.3:1</b>  |
| Brand text on app background   | <b>10.0:1</b> |
| White on comfort fill          | <b>2.1:1</b>  |
| Comfort text on app background | <b>7.2:1</b>  |

NOT SETTLED

- **No brand typeface.** The largest open question here.
- **Store screenshots** — 17 artboards still show the old accent and the placeholder icon.
- **The report's mind-line ink** is thin on white.
- **Voice** is documented but inferred from in-product copy, not confirmed.
